

beautiful always the your clothes a drug always that program
 When embedded in ECM verbs, “apparent” FSC can appear both in a subject-predicate and in a predicate-subject order (cf. (8)), while in a root way, they cannot appear in subject-predicate order (cf. (9)). This fact seems to suggest FSC cannot be embedded and what we have in these cases is an ordinary SC, given that BP FSC seem to have TP, as we can add a temporal adverb on it (cf. (10)). In view of the fact that we can have (11a) but not (11b), I will assume that FSC are in fact a root TP, without CP, that is, it is really “free”.

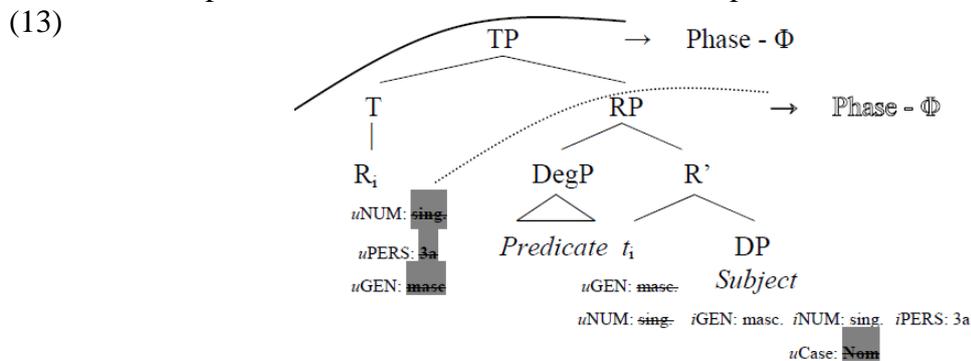

- (8) a. *Eu achei [horrível o dia]!* b. *A Maria achou [bonita a sua roupa]!*
 a'. *Eu achei [o dia horrível]!* b'. *A Maria achou [a sua roupa bonita]!*
 “I found awful the day/the day awful!” “Maria found pretty your clothes/ your clothes pretty!”
- (9) a. **O dia horrível!* b. **A sua roupa bonita!*
- (10) a. *Bonita a sua roupa ontem!* b. *Muito lindo o dia hoje!*
 pretty the your clothes yesterday very beautiful the day today
 “Your clothes were pretty yesterday!” “The day is beautiful today!”
- (11) a. *Hoje eu acho que a sua roupa_i ‘tava [t_i bonita] ontem.*
 “Today I consider that your clothes were pretty yesterday.”
 b. **Hoje eu acho [bonita a sua roupa] ontem.*
 today I think beautiful the your clothes yesterday

Taking all of these considerations into account, I will assume that FSC structure is the one represented in (12). What I am suggesting is that erasing of copula in BP is only allowed in (12) configuration, that is, a RP small clause emerged from a reverse predication, being selected by a root TP, adopting a configurational and nondirectional approach for SCs (Den Dikken 2006).

- (12) [_{TP} T [_{RP} PREDICATE [RELATOR [SUBJECT]]]

Once Den Dikken’s (2006, 2007) proposal: (i) do not consider C-T as a set (cf. Chomsky 2004), allowing that non-defective T has its own ϕ -features, and (ii) assume that TP can be a phase, *via* Phase Extension (raising of R to T), this framework seems to be more suitable for explain the empirical results we got earlier.

FSC derivation occurs as following: R selects the subject as its complement and after that the predicate as its specifier. TP enters in derivation and RP head is raised to T. This movement triggers Phase Extension from RP to TP, following Den Dikken’s (2006, 2007) proposal. Phase Extension solves problems related to Phase Impenetrability Condition. T enters into an Agree relation with the subject, since the predicate cannot count for intervention effects as it has no person feature in its composition (cf. Maximization Principle, Chomsky 2001, 15). Once EPP feature is optional in romance languages (Nunes 2007), derivation stops in (13) with all uninterpretable features checked and is sent to spell-out.

If the analysis proposed here is on the right track, it shows that FSC of BP seem to be an evidence that TP also can be considered a phase (and not only CP and v^*P , as considered in Chomsky, 2000 *et passim*), as already proposed, in a different and a independent way, in Gallego (2007) and Gallego and Uriagereka (2006).
